BREAST CANCER SCREENING PROGRAMME IN FINLAND

CANCER ANNUAL REVIEW 2017

Attendance for breast cancer screening has remained stable. There are, however, regional differences in the nationwide Finnish organised screening programme for breast cancer. To unify the programme, the national and regional steering systems need to be restructured. Additionally, developing further quality assurance for testing outside the programme is needed. In the future, information on social inequalities with respect to screening outcomes should be collected.

SUMMARY

In 2015 381,000 women were invited to breast cancer screening in Finland and 315,000 of them attended, 83% of invited. Approximately 97% of the screened women tested negative, 3% were recalled for further assessment and 0.8% were referred to surgery. Around 9,300 women were recalled for further assessment and 2,000 were diagnosed and treated with invasive breast cancer or carcinoma in situ under the programme. Attendance for breast cancer screening reduces breast cancer mortality on average by 33% compared to the situation without screening.

1. INTRODUCTION

The Finnish breast cancer screening programme started in 1987 and became nationwide in 1992. The aim of the programme is to reduce breast cancer mortality by early detection.

The screening programme includes personal invitations, mammography as

primary screening test and, if needed, further assessment (additional mammograms, ultrasound and biopsies) and surgery. Mammograms are taken from two directions for both breasts. Two independent radiologists read and interpret the images. If a tumour is suspected in either of the breasts, a consensus reading is performed.

The results of screening are notified by a personal letter. If further assessment are needed, the screened woman is personally recalled either by letter or phone.

The Finnish municipalities are responsible for organising the screening activities. They choose the screening performer, which can be the municipality itself or a private company. The screening tests are performed in screening units. The units send the screening invitations and perform mammograms and further assessment if needed. Diagnostic confirmation and surgery are performed in special health care. Mammograms and further assessment are free of charge for the screening target population, but an outpatient clinic co-payment is charged for treatments and examinations performed in specialised medical care.

Individual data from all phases of screening episodes are sent in electronic format to the Finnish Cancer Registry for monitoring and evaluation. Monitoring ensures the quality and effectiveness of the programme as well as identifies pertinent issues and bottlenecks in the screening performance.

The breast cancer screening programme's national target population consists of 50–69-year-old women who are invited to screening biennially. From 1992 until 2006, the national target population consisted of only women aged 50–59, and based on Government Decree on Screenings it widened up to 69 during 2007–2016.

The current monitoring report presents figures and tables on the coverage, attendance and results of the screening programme from the whole country and 21 hospital districts for the year 2015 and time series from 1992 onwards. These are based on individual screening invitations and visits derived from the data base of the Finnish Cancer Registry. The information on population counts stems from tabulations of the Population Register Centre.

2. BREAST CANCER SCREENING IN FINLAND

MAIN FINDINGS IN 2015

In 2015 altogether 381,000 invitations were sent and 315,000 women attended to screening (83%, <u>Table 1</u>). The invitational coverage in the national target age group, 50-69 years, was very close to 100% (Table 2). Approximately 97% of the screened women were tested negative and 3% were recalled for further assessment in the screening centre. Around 2,600 women (0.8% of screened) were referred to surgery and further assessment performed in specialised medical care (Table 3). The latter includes histological classification based on core needle biopsy or surgery and other specific examinations. Around 2,000 (0.7% of screened) invasive breast cancers and carcinomas in situ were detected within the programme.

All municipalities sent the screening data to the Finnish Cancer Registry. The histological response is missing for only about 3% of those referred to surgery.

COMPARISON TO EARLIER YEARS

The coverage of screening invitations has increased since 2007 due to the widened target population (<u>Figure 1</u>). Practically all municipalities invite the national target population, women aged 50–69, every two years. Furthermore, a part of municipalities widened the target population up to 69 ahead of time. Meanwhile the attendance for screening has started to decline slightly, from 87% in 2005 to 83% in 2015. The slope of decline has been similar in all age groups.

The average proportion of invitations to further assessment has remained similar over the years (Figure 2). The proportion is higher among the youngest age group of 50–54, partly because of no previous images to compare with. The proportion in this age group has also increased over the past decade (Figure 3). Women in this age group are however referred to surgery, as well as diagnosed with breast cancer, more unlikely than in older age groups (Figure 4, Figure 5). Breast cancer risk increases with age. As the target population widened, the amount of referrals to surgery and malignant findings have increased especially in the age group of 65–69. The increase is probably also due to the fact that this age group was invited to screening after a long break.

3. BREAST CANCER SCREENING BY HEALTH CARE DISTRICT

The invitational coverage and attendance rate vary between the health care districts. In 2011–2015 the range in attendance was 78–88% (Figure 6, Table 4). It is known that the attendance is lower in big cities than in other parts of Finland.

There has also been variation in the screening results (Figure 7, Figure 8, Figure 9, Table 5). The proportion of recalls varied between 1.4 and 4.4%, the proportion of referrals to surgery between 0.5 and 1.0% and the proportion of screen-detected cancers between 0.4% and 0.8%. The regional differences are due to differences in both the background risk and diagnostic criteria.

4. COSTS OF THE SCREENING PROGRAMME

According to the estimation of the Finnish Cancer Registry the average costs of the screening programme were approximately 30 euros per screened woman in 2015. These included e.g. invitations, mammograms, further assessment performed in the screening centres, archiving, and the costs of registration. However, there were regional variation in the screening prices. The total costs of the screening programme, regarding the before mentioned expenditures, is thus estimated to be 10 million euros yearly. The estimation does not include the costs of diagnostics and treatments after the referral.

More than 100,000 mammography examinations are performed outside the screening programme. Mammograms are performed because of a symptom or other indication, sometimes because of a benign transformation, as well as in the diagnostics and surveillance of breast cancer patients. Apparently, mammograms are also performed for symptomless women as a clinical or screening-like examination. The amount of these so called opportunistic tests is unknown. The unit costs of testing outside the programme are estimated to be considerably higher than within the programme.

5. THE BURDEN OF BREAST CANCER AND THE DETECTION MODE

Every year around 5,000 Finnish women are diagnosed with an invasive breast cancer and 400 with carcinoma in situ. The prognosis of breast cancer is good: the 5-year relative survival is as high as 91%. Deaths caused by breast cancer–the prevention of which the screening programme specifically aims to–is slightly over 800 a year. Cancer cases registered as carcinoma in situ cause only a couple of deaths yearly.

All breast cancers diagnosed in 2010–2014 were classified with respect to organized mammography screening. Invitation to organized mammography screening is currently sent to all 50–69-year old women every 20–26 months. The data has been limited to

those municipalities that sent their screening information to the Finnish Cancer Registry.

• "Under target age" have not yet been invited to screening. Most women in this category are under 50 years old.

• "Above target age" have never been invited to screening due to their old age or time since the last invitation exceeds 26 months.

• "Non-participants" have received an invitation within 26 prior to their diagnosis but they had not attended screening.

• "Screen-detected" breast cancers are diagnosed within 6 months of the screening attendance after a positive mammography, referral examination and surgery.

• "Interval cancer" is diagnosed after negative mammography or negative further assessment within 26 months after attendance to screening before next screening, or after negative surgery within 6–26 months after attendance to screening before next screening.

• "Non-registered" breast cancers are diagnosed in women who should have received an invitation to screening but it has not been registered.

About 34% of invasive breast cancers and carcinomas in situ were diagnosed within the screening programme (Figure 10, Figure 11). The proportion will probably continue rising when all women aged 50–69 have entered the programme. About 50% of carcinomas in situ were diagnosed within the programme. This suggests that mammograms are common also outside the programme.

6. THE EFFECT OF ESTAB-LISHED SCREENING ON BREAST CANCER MORTALITY

In a follow-up study regarding years 1992–2003, organized breast cancer screening decreased breast cancer mortality by 22% compared to a situation without the programme. Breast cancer treatments have improved with time and breast cancer patients survive well. When coming to 2010s, it's therefore essential to evaluate whether screening still decreases breast cancer mortality.

In a study published in 2016, attendance for breast cancer screening between cases and their comparable controls was compared. Cases were due to women aged 50–84 years who had died from their breast cancer. This large and long-term registry study included 1,907 cases and 18,978 controls in 1992–2011. All women in the data had been invited to screening at least once during their life.

Attendance for screening decreased breast cancer mortality by 33% compared to situation without screening (<u>Table 6</u>). Thus, the impact of screening on breast cancer mortality has not changed with time.

7. BENEFITS AND HARMS OF SCREENING

The Finnish breast cancer screening programme reduces mortality from breast cancer among the screening participants (see section 6. The effect of established screening on breast cancer mortality). The coverage of the programme has increased significantly in the past years due to the widening to women aged 60–69 years. Based on this,the decline in breast cancer mortality can be expected also among the older women. A screen-detected tumour is found at an early stage which enables a good response to treatment and that lowers the aggressiveness and harms of the treatments.

Besides these major benefits, screening may also cause harm. In Finland, approxi-

mately one out of six screening participants is needlessly sent for further assessment if they attend screening regularly at ages 50–69 years. Additionally, approximately three out of one thousand women will develop a breast cancer after negative screening test before the next screen. Most of these so called interval cancers develop after the screening so these women were not recalled for further assessment. However, interval cancers are diagnosed also for women who were recalled.

Screen-detected breast cancers tend to be slow-growing and a proportion of them would not have surfaced clinically in the lifetime of an individual without screening. Based on several studies, these so called overdiagnosed carcinomas constitute, however, at maximum 10% of all carcinomas detected by screening.

8. CONCLUSIONS AND RECOMMENDATIONS

Finnish breast cancer screening programme has been effective and the key performance and outcome figures are in line with other countries. However, there are significant differences between different organising units in the quality of diagnostics and the practices used. Thus, the balance between benefits and harms may differ among the screening performers. To unify the programme, the national and regional steering boards need to be restructured. The objective of the steering board could be both to improve the screening programme and also to perform quality assurance for the opportunistic and other testing activity outside the programme.

The quality indicators of service use, diagnostics and screening results should be improved and followed, also taking into account the use of opportunistic services and chains of care. Also, effectiveness and cost-effectiveness of screening should be regularly evaluated. Screening attendance should also be improved. Invitational practices have a great impact on the attendance rates. Time and place for the screening visit should be indicated in the invitation letter, alternative appointment times should be available, and a reminder letter should be sent to non-attenders.

Quality indicators and effectiveness should be evaluated for the organized screening programme as well as services outside it with respect to socioeconomic status and other variables measuring social inequality. Interesting key performance figures are e.g. coverage, attendance, discoveries, and the integrity of screening and diagnostic episodes. Residential area, municipality type, and distance to health care services could be basis for developing indicators of regional inequality.

Information on prices of screening contracts in organized screening and of mammography used outside the screening programme would be useful for the future evaluation of costs and cost-effectiveness. Chain costs of patient care should also be collected. All opportunistic tests, further assessment and diagnostic confirmation should also be registered to the Finnish Cancer Registry congruently. Data systems in health services should be able to record entire chain of care without any gaps. This would make it possible to trace and report pathways all the way from routine testing until treatment and follow-up.

TERMINOLOGY

BIOPSY	Sampling of cells (fine needle aspiration biopsy, involves
	cytopathology) or a tissue sample (core needle biopsy,
	involves histopathology) removed from the living body.
CANCER INCIDENCE	The number of new cancer cases per population
	at risk during a given period.
COVERAGE	Proportion of those invited to screening
	(invitational coverage) or those attending
	(screening coverage) of the whole target population.
FALSE POSITIVE	Woman is recalled for further assessment.
SCREENING RESULT	or referred to surgery but the result is negative
	(no invasive breast cancer or carcinoma in situ of the breast).
FURTHER ASSESSMENT	E.g. additional mammograms, ultrasound, pneumocystography,
	galactography, fine needle aspiration biopsy and core needle
	biopsy, or the combination of some of these.
MALIGNANT FINDING	
CARCINOMA IN SITU	Precancerous tumour of the breast (ICD-10: D05).
INVASIVE CANCER	Breast cancer (ICD-10: C50).
METASTATIC TUMOUR	Breast tumour caused by a cancer that has
	spread from a different part of the body.
MAMMOGRAPHY	An x-ray of the breast.
EXAM (MAMMOGRAM)	
MORTALITY	The number of deaths per population at risk during a given period.
OPPORTUNISTIC TESTING	The testing of nonsymptomatic persons outside the organised
	screening programme (in private or public health care services).
	Also symptom related testing and patient follow-up is performed
	outside the screening programme.
OVERDIAGNOSIS	The diagnosis of a cancer or a precancerous tumour that
	would not affect the person's health during her lifetime.
SCREENING PROCESS	The progression of the screening episode from the definition
	of the target population and sending invitations all the
	way to testing, possibly further assessment, treatments
	and patient follow-up.
